Subject: What collection to use to achieve this?

Hi folks,

I have a collection of objects in the system. Each object has a name, which is a string. I'd like to have a collection of associations, which maps a string to an object. From the UDP or TCP socket, program will receive a string which contains the object name, I will then use the object name to index the object without long switch/if statement, and pass the rest of the input string as function call arguments?

I am a newbie. In this case, what kind of collections of associations to be used?

Thank you!

Best Regards
David
