DropGrid is a "DropList" based on GridCtrl with some new capabilities:

it can have more than one column
it is resizeable
it can display "row values" as a display value
it supports dynamic searching. just start typing when dropgrid has focus. All rows that contain a pattern will be highlighted. F3 moves the cursor to the next matched row.

Of course DropGrid returns one key value, which can be set in SetKeyColumn(int col).
Please open main.cpp in DropGrid package to see how to use it.
I'll make a full documentation a little bit later.
DropGrid can be used for example to show complex database query result without grid/array placed on the dialog layout.
