What works in Windows is that files are displayed with icons dedicated to their types. Means, .txt files have different icon than .xls and from .exe the icon is extracted.

This is what I would like to know how to implement in Ggnome...

Mirek

GTK uses an in-tree copy of this:

<http://webcvs.freedesktop.org/mime/xdgmime/>

But GtkFileChooser doesn't expose any of it as a public API
