BTW: what about `std::vector` and your own allocator?

If you, for whatever reason, use the container API extensively enough to make this worth of effort. (I didn't use `stdlib` extensively enough to be sure, but I think all the standard containers allow to use your own allocators?? Maybe I'm wrong.)

I always liked classic pointer and arrays more than those complex templates, but in PHP in connection with "foreach" I started to appreciate them a little bit. Still whenever I know enough about my array (i.e. fixed size, fixed type, small scope of code using it), I prefer classic `[]` array without that additional fuss and burden around. Usually in new code I don't know enough, and flexibility of vector allows better refactoring and earlier bug catching.
