Idea 2: Have a mapping of sequences to table names from the .sch file.

Something like:

```
String seq = m_session.GetPKSequence(TABLENAME)
```

and we could use it like this:

```
...insert statement...  
sql.GetInsertedId(seq)
```

and/or

```
sql.GetNextId(seq)  
...insert statement...
```

Idea 3: Create a separate insert function called InsertSelect which will return 0 (or -1) for a failed insert and otherwise return 1..N which would be the last inserted id using the method described in the above post. So this would mean we would have 1 insert with no overhead and 1 with the overhead of getting the inserted id and returning it.
