Building deb/rpm every night is good for testing the distribution/deployment mechanism, so in case it gets broken over time, it will be noticed ASAP.

But I agree there are no "end users" for nightly rpms/debs, except some occasional tests or in case you want to know if some bug will be fixed by next release. Still I think if we have enough CPU power to do nightly full packages builds, it's worth of doing them.
Also I think there should be enough CPU power to run automated tests, ideally "per commit", or at least continuously/daily in case the commits will be too frequent to build per commit.
