Subject: Different results from same code&settings

Hi,
I'm working on a project in U++ for about two months with no problems whatsoever, but lately I've seen some weird things to happen:
I compile main package, execute the program and everything works as it is supposed to. Then I compile it again, without any changes in code and it crashes in the middle of execution with "Invalid memory access!" error. After that, I have to replace the files from my backup and restart the ide to make it work again.
I tried to find what exactly causes it, but with no luck... I reproduced this behaviour in version 2008.1 and also svn.324 (from .deb package), both under Linux.

Had anyone encountered something similar or have you any idea what could be tha cause? Im really confused...

Thanks, Honza
