1. So, if I've understood, a complex interface with many classes should be merged in the constructor of the application.

I hope to be able now to add a tabbed window (with 4 pages) between the menu and the status bar.

Because each page contains several widgets I'm afraid that the final constructor of the application will become a mess.

I hope to write for each page a class and simply invoke it in order to simplify the constructor. Perhaps I must create just a big widget to attach it somewhere in the page. In Motif this was possible.

- 2. Are there example about the creation of a Widget?
- 3. (Please be patient if I said silly thing... I'm just starting)

Luigi

- 1. Complex interfaces should be more or less evenly distributed among classes and their constructors. That's why classes exists!
- 2. I personally know 3 main ways of creating widgets:
- 2.1. As Mirek mentioned here with Layout Designer
- 2.2 Program everything yourself by hand
- 2.3 Copy code from *.lay files and create your own programmed classes.

Which case you would like to discuss?

3. Don't worry about our patience! By asking questions you are helping future generations of U++ users. So, please ask more often!
