I'm sorry for unclear formulation, SaveAs always worked perfectly. What I meant to say was that it would help when opening files differing only in suffixes.

One more example where I would use preselected filename came to my mind: Suppose I have an application which handles some data file and configuration file telling it what to do with those data. Now if user already opened configuration file, it would be a nice feature to preselect a corresponding file when opening the data. (For example based on filename of configuration file - perhaps with a check that it exist).

Idea with Preselect field sounds good to me. If you could implement it I would really appreciate it. Just hope it's not too much work, I wouldn't want to distract you from more important things
