Hi kohait,

The only comment I can give you is that I actually never needed such thing. I think there are two possible cases: 1) You need to disable some specific callbacks, or 2) you need to disable callback on a specific place of your code. Both are very easily solvable even without `Callback::Disable()`. For 1) it is just adding `"if(DoNotExecuteNow) return;"` on the beginning of the callback functions you might need to disable. For the second case, it would be similar, but the if would be outside of the call, something like `"if(!DoNotExecuteNow) WhenSomething();" .`

IMHO there is not much need for changes. Actually I never even used the `Clear()` method

Best regards,  
Honza
