Hello Jibe

Thanks for your reply and the helpful tips.  I have no issues with French and I think I will follow up on your links.

From my viewpoint, this is what I think I need to do
-  Micro-controller talks to PC via Serial RS232 port using a simple serial protocol.
-  Application on PC acts as a client/maybe a web-server to serve up the pages of information that can be populated with information from the micro-controller board.
-  Internet browser on some remote PC can access this webpage and modify/view status of the board.(interact with webserver app above)

This is the exact type of thing I'd like to learn how to do.
