Hello jibe

Further to my investigations, I have been able to narrow down my problem area. What I think I need is a way to make my pc into a webserver running my own application that can collect the data from my board.

The micro-controller board is a custom built one(that's typically what I do for a living). It communicates with the PC on a RS232 or USB port and that part is not the problem I have. The data will be a few bytes across a second. I only need to find a solution of how to take some information from my pc and present it on the internet(for this I think my pc needs to become a webserver). So, the suggestions I have seen till now involve EasyPHP, Apache and Perl among others. However, this is beyond my league at this point in time and I am trying to learn up fast.

I really appreciate your help on this and know I have support in trying to find a workable solution.
Thank you

Regards
Jerson
