Hi,

This is a very simple problem : we have just to replace HTML entities with accented letters, or the contrary (HTML2String() or String2HTML()).

The problem is just to have something as complete as possible, with the different kinds of HTML entities (string, decimal or hexadecimal) and all possible entities (accented letters, symbols etc.). I'm surprised that nobody worked on it, and to not find something complete in source codes of different languages... If you know something, please tell me where to find it !

I wrote a function with a part of entities... This covers my needs for now. If I have time, I'll make it more complete (and better coded) and share it.
