sergeynikitin wrote on Fri, 02 December 2011 21:22I send to colored column 2 values from 2 columns:

for example: "2:10"

And in display method :

I split this combined value (function Split()) and use 1-st for display value 2-nd for color.

Prevet Sergey,

This is a tricky solution that I will use if no other solution will arrive. But I hoped in some more natural way. For example some variable/pointer within Display that has access to the whole row of the ArrayCtrl.

For example the competitor, , GridCtrl use 'parent'. Then parent->Get(MYCOLUMN) permit to get different value in other column. It is a very handy solution .

Each time is a struggle for me to decide wich ctrl to use.

Luigi
