OK! Please say from what table DUMP(SQL[NAME]) read data in read cycle

I think, it depends from current select. Based on the logs, by the selection order:

SQL[0] from WORKER.NAME

SQL[1] from WORKER.LASTNAME

SQL[2] from PLANT.NAME

SQL[3] from PLANT.ADDRESS

Therefore, SQL[0] == SQL[NAME] from WORKER table here. It's like finding index by the Sqlld name.

Where went easily-readable code U++?

In this case it is better to write

WRK_NAME and PLA_NAME

(Exceptions are cases when not myself create the Database, and connected into the already existing DataBase.)

.

Agreed, this might help also. I just did it with my current understanding of the U++ source code.

PS

By the way, sorry for the tone (if it seemed overpriced).

Nothing personal. I treat you with great respect.

No problem. Interesting topic.
