hello, i'd love to read about all those useful things you can do with that plugin.

My planned task is as follows:

i'd like to read in a .db file created by another sqlite db (what i'm coding is an external module for that project.).

I tried to get behind the usage by looking at the example over and over, tweaking here and there but without success (my bad).

So before i rush into try n error or try to get behind it reading the code behind the plugin (which i am going to do now) i'm asking here for a solution covering all to enough odds that might hit me. Thanks in advance.

edit: try n error luck

now i have to dig into the syntax for reading stuff from it again the only help is assist++ first question is regarding `sql.fetch(Fields)`

how do i throw a field in there? `sqlid` style? would result in ambiguous overloaded function call because of string is not within scope hm?
