guess distros don't have this libbpg package yet so it's best to include it in u++ and compile it static anyway. for 16x16 images it isn't doing much good, but for example ide/theide48.bpg would take up 780 bytes at the ordinary compression. I know png isn't lossy, but a program with lots of pictures might consider to save on space this way.

according to <http://bellard.org/bpg/> this format is offering better quality than jpeg at the same filesize. so you could consider it to be a better compression. maybe equipt icon-editor with that output-format and add an interface to tune the compression while displaying both versions side by side? of course the actual file-creation would only be performed during compilation, maybe directly into the ressource-file...
