Having clean options in umk may be nice, but I don't think this should stop you.

If the umk builds into "out" directory, same as IDE, you can safely delete whole subdirectory with some shell script.

hmm..

Although now I think you may have hard time to extract correct \$out subdirectories names without umk (so you would end up with hardcoded local paths in your script), how does it work in VS?

Does the umk calculate it's own out directory and then just puts final .exe into some \$target, or does the VS options provide also path for temporary .obj files?
