Subject: How does DropGrid::Format() work?

Hi,

I am trying to use DropGrid to edit cells in GridCtrl. In examples it is always used in such a way that no column is created (no call to AddColumn) and rows are added using Add with two arguments (first id, second printed value). It works ok.

However, when I create columns using AddIndex and AddColumn, DropGrid::Format always return Null. Is there easy way to set it up to work as a converter in such case (i.e. without creating derived class and overriding Format)?

Jakub
