You must have something else messed that is not visible from code you have posted.

I have prepared simple demonstration for you. There are two additional tricks demonstrated:

- ID1 is 'plain and simple' raw C++ example. It 'renames' ID1 to represent different name.
- ID2 is similar but using SQLID macro so that you do not have to repeat the name of columns as string literal
- ID3, NAME, SURNAM are defined using 'multi-include' trick, means you just have to list ID in single place (ids.i file here)

Hope this help. If not, you are beyond help :)

Mirek
