Well, in Java world you should always provide also the Locale to be used by the formatter. So then you do thing like `str = Format(Locale.US, "%.2f", value)` when you are exporting data for machine, or you call with other (none=default) to get formatting for human output, which can include also things like thousands separator/etc (and is not suitable for machine export/import).

Actually, that is in U++ for ages:

```
String Format(int language, const char *fmt, __List##I(E__NFValue));
```

Only you have to use U++ formatters instead of C ones...
