Subject: Non-modal close button?

If a non-modal window gets created, a close button gets added to the title bar as follows:

If the virtual method void Close() gets over written for the non-modal dialog window, the non-modal dialog window closes along with the rest of the application. I've attempted making use of DoClose(), but that doesn't also give the intended consequences for closing the dialog window and executing some other house cleaning chores.

How does one reference the title bar close button, or apply a THISBACK so as to take action for the user's request?

Peter
