No downside but it's ugly?

Better to:

- add another array in Package class:

```
Array<OptItem> library_path;
```

- add in PackageEditor::PackageEditor()

```
Add("Internal include path", actual.include);
```

```
Add("Internal library path", actual.library_path);
```

- Make actual.include like other options in Package Organizze (I mean, with rw access to 'When' textfield so it can be flag activated/distribution specific)

- Then use those Package variables to fill Makefiles and default .bm files if those flags are active

?

I didn't find where "Internal include" (package.include) is used in TheIDE, so I renamed it "Internal include path".
