I understand that this is initial version, so the version management is not must. However, we need to add updates possible and let user even download custom commit/branch/version. I do not see that ones downloaded branch will stay forever without any updates or possibility to change to certain commit. I know that you can remove and then uninstall, but this is not very handy...

You can always create normal nest and git clone anything there.

Let's assume that I fixed the problem with my module. Then what? In above case with tag the user can not download anything besides the release-1.10.0. I think option like "Install certain commit/branch/tag.." could work in our case. This will remove whole repo and download repo with certain commit. Clear and simple solution.

- a) I think it should be other way around. master is always current stable version. If you want to experiment, experiment in branch.
- b) Well, I actually agree there is an utility in this. But I do not yet see how to do it right. Should e.g. there be some global branch names? How will user know what difference is between branches?
- c) Also, UppHub does not need branches listed - that information can be loaded from the git.

There is BTW one other much more serious problem and that is a release of user's application. I have solution for that...
