nicomesas wrote on Fri, 06 October 2006 18:37I have throughout been studying this class the day and I believe that I have reached some conclusion.

The host that this class needs, is not like in other objects acceding to protocol smtp; with this class we directly sent the mail to the server of the mail recipient.

Then, the problem is in finding out which is the name of host for a given server, since if we sent a mail to alguien@gmail.com, host IS NOT gmail.com. I Think I need to find the MX record from gmail.com.

I have found some codes GNU useful, but finally I have remained with one found here
http://viewcvs.pointblue.com.pl/index.cgi/gj/sendemail/mx.c

I have written with it an example that I'm attached here, so that we pruned to follow the conversation between all.

Nico

PS. I don't know if the sample works in windows, because it use the (unknow for me) 'resolv' library

In fact doesn't work
It stopped to
#include <netdb.h>
I try to get it
