
Subject: [Proposal] GLCtrl and textures

I get the dreaded white texture of death rendering a quad and I discovered the only place I can get it to work is in GLPaint, but that kind of defies the purpose of creating a texture beforehand and binding it. I looked through the source for GLCtrl and could find no obvious hook for getting calls in right after a gl initialization call so I added a callback WhenGLInit and call it here:

```
void GLCtrl::ExecuteGL(Event<> paint, bool swap_buffers)
{
    MemoryIgnoreLeaksBlock __;

    glXMakeCurrent(s_Display, win, s_GLXContext);

    ONCELOCK {
        glewInit();
        WhenGLInit();
    }

    paint();

    if(swap_buffers)
        glXSwapBuffers(s_Display, win);
    else
        glFlush();

    glXMakeCurrent(s_Display, None, NULL);
}
```

Textures work fine after that. Is there some other hook that I can make calls right after GL has been initialized/context has been created and I simply missed it? Is there a more appropriate way to do this?
