Right :) But you can do this with:

grid.GetWidth(my_column_index) - grid.GetWidth(my_column_index - 1)

But be careful with the moment you're calling those functions. If you add columns with widths expressed as proportions then the actual pixel width is not set until first grid paint is made. Don't really know what's your use case but you shouldn't be interested in column width's in most cases until you want to paint sth inside the cell. But then you need to provide your own Display implementation in which current width and other properties are available. So that's another story.
