lundman wrote on Tue, 05 December 2006 01:37Hello again!

Since I now inhereted the OsX machine itself when my colleague quit, I thought I would check on how things are now. I managed to port it to OsX fine last time, but it had a few graphics glitches, but otherwise fully functional.

I have grabbed 611-dev4 to play with, here is a list of issues I have resolved, and moved on with:

Core/Core.h:

```
#ifdef flagOSX
    #define PLATFORM_OSX
```

BTW, maybe we should call this platform as OSX11, because this is not "real" MacOS X... What do you think?

```
/usr/bin/ld: Undefined symbols:
TTFReader::TTFStream::operator%(int&)
TTFReader::TTFStream::operator%(unsigned int&)
TTFReader::TTFStream::operator%(short&)
TTFReader::TTFStream::operator%(unsigned short&)
FreeDll(void*)
LoadDll(String&, char const* const*, void* const*)
vtable for BMPEncoder
DumpLanguage(int)
DumpAlign(int)
DumpColor(Color)
collect2: ld returned 1 exit status
```

Looks like PdfDraw (but than one you added to uses?) and plugin/BMP are not present - both are conditional uses for X11. Strange...
