Hello,

The SQL_MySql app performs all of its operations as part of main. What I am trying to do is access various SQL actions (insert, update, delete, select), from within functions that are part of the main window class. I believe that i could simply use the "Execute" function, but I would prefer to use the functions in the Sql class.

As a side note, I am trying to use a schema file similiar to the one in the SQL_Sqlite3 example, however it doesn't seem to create the table or, if I create the table independantly, update the records in the table.

Thanks,

Dave
