OK, I understand now.

This seems to be a good idea.

The other problem with Java is, that it had to have very stable, frozen APIs, because after deploying a new version of JVM, the apps, developed to the old one had to continue working. But in real life, this is not true. There are servers in enterprise environment with a lot of JVMs.

But with this U++ "runtime", the compiled binary would be there.

But thinking about this, I think it is much simpler to give a simple binary to the user.
