Tom1 wrote on Tue, 13 March 2007 08:18Update to the above:

Did some further digging...

It appears to me that the Ctrl::ScrollView() invalidates the rectangle once and then when the WM\_PAINT comes, the Ctrl::SyncScroll() causes the invalidated rectangle to be scrolled effectively doubling the invalidated area.

I think the ScrollView should not invalidate the area but wait for the SyncScroll to do it. Or are there side effects to this approach?

Any ideas...?

-- Tom

Well, there is one important thing to understand here:

ScrollView is just a form of Refresh. There is no guarantee about what is the invalidated area.

ScrollView basically says that the area *\*CAN\** be repainted while reusing existing content and moving it somehow. Implementation can but does not need to use this knowledge.

This all was decided to resolve problem with combined scrolls, scrolling child widgets and many other issues. Current implementation is maybe a little bit too conservative as it sometimes repaints bigger areas than needed (but in practice, this is little problem).
