I want user data (like different menus) to be chosen and loaded from different files...
What would be needed for Esc "read_file" or "include" or "import" or..?
Is there an existing possibility or do I/we need one more func to EscStdLib?

Esc std lib already has some file streams... However, there might be problem with path.

Actually, I see you are trying to develop some very very smart project template. OK, but unless it will solve some real and important problem, I will not care about extending .upt (which solves real problem and works quite well for what it was intended).

Path is not a problem (at least at the moment...).

But I want to "extract"/load some variables. Something like "evaluate" from string might be useful?
Or is there a workaround?...

No, "string evaluate" is not available.
