Hello,

I'm trying to understand what is line 447 in the method XmlParser::Next() for.  
String aval = FromUtf8(~attrval, attrval.GetLength()).ToString();

It is causing major performance problems when parsing big xml files.

What it is doing, it is basically converting StringBuffer --> WString --> String.

I guess it is supposed to retrieve a valid UTF-8 sequence.

Is it possible to replace this conversion with something more performance friendly?

Regards,

This appears to be a support for non-UTF8 applications.

Will be easy to optimize, good catch.

Should be now fixed.

In the process, I have also added support for <?xml encoding="

Thank you! XML parsing is two times faster now.
