Hello community,

When we have to deal with OpenGL, it is often interesting to load a certain amount of data (Texture / Vertex / Shaders) before rendering a scene.

Nowaday, to load those things, I must declare a boolean in my derived class of GLCtrl and use it to perform many load at the first loop in GLPaint, as Follow:

```cpp
bool isLoaded = false;
virtual void GLPaint() {
    if(!isLoaded){
        /* Loading Few things ! */
        isLoaded=true;
    }

    /* Code to perform draw */
    Refresh();
}
```

Even if this way of working is functional, Having to write many and many code and routine of loading in GLPaint() is annoying and don't help in code readability.

That's why I started to dig out the GLCtrl to implement a virtual function called Initialisation() which can be overwritted. The purpose of it is to be called right after OpenGL context Initialisation. My first way of doing this was Adding the call of function here (GLCtrl.cpp line 33):

```cpp
void GLCtrl::Init() {
    Transparent();
    #ifdef PLATFORM_WIN32
    pane.ctrl = this;
    Add(pane.SizePos());
    #endif
    restore_gl_viewport__ = SetCurrentViewport;
    Initialisation();  //--> I call Initialisation Here
}
```

But (It seems) due to Ctrl creation, the function which is called at this moment is the non overwritted Initialisation() from GLCtrl and not the one I have overwritted in my derived class from GLCtrl.

So my next try was to implement it here (Win32GLCtrl.cpp) :void GLCtrl::GLPane::State(int reason) {
```
    DHCtrl::State(reason);

    if(reason == OPEN) {
```
HWND hwnd = GetHWND();
CreateContext();
HDC hDC = GetDC(hwnd);
if(!SetPixelFormat(hDC, s_pixelFormatID, &s_pfd))
    return;
ReleaseDC(hwnd, hDC);
static_cast<GLCtrl*>(parent)->Initialisation();  //--> I call Initialisation Here

This time, it call the overwritten Initialisation() but OpenGL Context is not yet well initialised, consequence is every call to OpenGL api (all call to allocate some memory in vram) fail!

So far I dig, I didn't find the proper way of adding this function, so I need your help! If someone have an idea...

Thanks in advance.
Best regard

Xemuth

I think the problem is that context is created but not associated with current thread.

Try with ExecuteGL method...

That said, doing this in GLPaint actually seems fine to me.

Hello Mirek, you are right, doing this kind of thing work:

```cpp
def GLCtrl::GLPane::ExecuteGL(HDC hDC, Event<> paint, bool swap_buffers):
    {
        static bool HaveBeenInitialised = false;
        wglMakeCurrent(hDC, s_openGLContext);
        if(!HaveBeenInitialised){
            static_cast<GLCtrl*>(parent)->Initialisation();  // --> I call Initialisation Here
            HaveBeenInitialised = true;
        }
        paint();
        if(swap_buffers)
            SwapBuffers(hDC);
        else
            glFlush();
        wglMakeCurrent(NULL, NULL);
    }
```

mirek wrote on Wed, 04 March 2020 13:06 That said, doing this in GLPaint actually seems fine to me.

Yes, it work aswell but the idea of having a visible boolean just to do some action at the first loop of drawing is disturbing me :twisted: (the fix I did in ExecuteGL(...) is basicly the same things but user don't see it :d Is it possible to add it to the GLCtrl code or you prefer stay like that ?

Thanks in advance
Best regard !

For I prefer it to stay as it is....

Do not worry Xemuth. With your control totally developed, GLPaint will be scarcely used.
