This sample (for latest SVN) code fails under FreeBSD

```
#include <Core/Core.h>

using namespace Upp;

CONSOLE_APP_MAIN
{
 HttpRequest::Trace(true);
 HttpRequest http("http://google.com"); //fails with almost any sites even w/o redirect
 String s = http.Execute();
 SaveFile("1", s);
}
```

It logs error:Quote:HTTP START
Starting status 2 'Resolving host name', url: google.com
HTTP StartConnect
HTTP AfterConnect
Starting status 6 'Sending request', url: google.com
HTTP REQUEST google.com:0
HTTP request:
GET / HTTP/1.1
URL: http://google.com/
Host: google.com
Connection: close
Accept: */*
Accept-Encoding: gzip
User-Agent: U++ HTTP request

HTTP Execute: Sending request
HTTP retry on error socket(5) / send: Socket is not connected
Starting status 1 'Start', url: google.com
HTTP Execute: Start
HTTP START
Starting status 2 'Resolving host name', url: google.com
HTTP StartConnect
HTTP AfterConnect
Starting status 6 'Sending request', url: google.com
HTTP REQUEST google.com:0
HTTP request:
GET / HTTP/1.1
URL: http://google.com/
Host: google.com

Connection: close
Accept: */*
Accept-Encoding: gzip
User-Agent: U++ HTTP request

HTTP Execute: Sending request
HTTP retry on error socket(5) / send: Socket is not connected
Starting status 1 'Start', url: google.com
HTTP Execute: Start
HTTP START
Starting status 2 'Resolving host name', url: google.com
HTTP StartConnect
HTTP AfterConnect
Starting status 6 'Sending request', url: google.com
HTTP REQUEST google.com:0
HTTP request:
GET / HTTP/1.1
URL: http://google.com/
Host: google.com
Connection: close
Accept: */*
Accept-Encoding: gzip
User-Agent: U++ HTTP request

HTTP Execute: Sending request
HTTP retry on error socket(5) / send: Socket is not connected
Starting status 1 'Start', url: google.com
HTTP Execute: Start
HTTP START
Starting status 2 'Resolving host name', url: google.com
HTTP StartConnect
HTTP AfterConnect
Starting status 6 'Sending request', url: google.com
HTTP REQUEST google.com:0
HTTP request:
GET / HTTP/1.1
URL: http://google.com/
Host: google.com
Connection: close
Accept: */*
Accept-Encoding: gzip
User-Agent: U++ HTTP request

HTTP Execute: Sending request

Very strange bug.
Proceeding with investigation...

P.S. Tested on defferent systems with different FreeBSD versions with the same result.

It works with step-by-step mode, when breakpoints are fired after each internal iteration within HttpRequest::Execute()

It looks like the code lacks some kind of delay (really got to find out why). Still adding small delay makes it all working:

```
bool HttpRequest::Do()
{
 Sleep(10); // <-- delay added, and the code works
 int c1, c2;
 switch(phase) {
```

That is similar to a socket connection with client/server.

With Win or Ubuntu with C++, Java, Python, etc. there is time involved.
Serial Port connections also require Sleep(?).

The amount of data sent or received by a Request has little effect.
It is the time required between each packet sent or received.

Hello, Neil!

Frankly speaking I just did not catch your point.
We have following simple code:
```
 HttpRequest http("http://google.com");
 String s = http.Execute();
```

This code works under Windows. But fails under FreeBSD.
My point is it MUST be working under FreeBSD as well. This is how cross-platform calls work.
You agree, aren't you?

Hi Paval

Yes I agree on cross-platform.

I have never tried FreeBSD.
Maybe that OS is lacking something that is necessary.

Take Android as an example which is lacking in many respects.
The Java app I work with tried porting to Android but have dropped it.
"The WW Android effort has stopped, BTW."
 http://forum.worldwindcentral.com/showthread.php?t=35031&amp ;highlight=Android

My post was just trying to show the necessity of time for any data transfer.

If Win, POSIX, MacOS work but FreeBSD does not then it could be considered a 'bug ' in U++ but trying to support ALL OSs like Android would be a real chore.

It's good you figured out what the problem was and got it working.

Neil

The problem IS NOT solved.
I wonder what U++ authors will answer.
The proposed Sleep calls are no more than dirty hack and finally the origin of such behaviour is

unknown. Besides even the hack proposed doesn't always work which means that internal cycles lack some necessary (under UNIX) delays. Investigation continues.
I'd greatly appreciate any practical theories what could it be.

OK, finally managed to find a possible cause of this misfunction. In simple words, under FreeBSD, connecting socket didn't finish at the moment when we start sending data through it. Which resulted in failure with error code "Socket not connected".

So here is my solution which seems to work but may be not that good.
(Core/Socket.spp)

```
bool TcpSocket::RawConnect(addrinfo *arp)
...
//@445 +++
    if (GetErrorCode() == SOCKERR(EINPROGRESS))
     WaitWrite();
//    +++
```

If you know better solution how to detect the need and wait socket connection, please propose it.

Ha! I know that there are differences in handling this in Linux/Windows. I was not aware that BSD is going to be different as well...

It indeed is not that good. Anyway, perhaps it would be possible to use WIN32 handling (I think it is quite likely that Win32 modeled its non-blocking sockets model after BSD and it is Linux who diverged). Could you try that?

Mirek

Yes, I'd like to help with that, but for now couldn't find how to change sources the way you proposed. The RawConnect() function doesn't contain any ifdef WIN32.
If you tell me what to change (or just give me a clue) I'll try to.

I think that the real stuff is in "WouldBlock" method - this one is supposed to return "true" if connection is not yet established.

After a bunch of experiments I've finally come to code which works under one of my test FreeBSD

systems I currently work in. Tomorrow I'll test it under different FreebBSD system to be absolutely sure about it.
For now, here is WouldBlock() function which seems like a solution:

```
bool TcpSocket::WouldBlock()
{
 int c = GetErrorCode();
#ifdef PLATFORM_POSIX
 #ifdef PLATFORM_BSD
 if(c == SOCKERR(ENOTCONN))
  return true;
 #endif
 return c == SOCKERR(EWOULDBLOCK) || c == SOCKERR(EAGAIN);
#endif
#ifdef PLATFORM_WIN32
 if(c == SOCKERR(ENOTCONN) && !IsNull(connection_start) && msecs(connection_start) <
20000) {
  LLOG("ENOTCONN issue");
  return true;
 }
 return c == SOCKERR(EWOULDBLOCK);
#endif
}
```

Excellent, looks like out theory about Win sockets modeled after BSD is sound.

Anyway, in that case, we will probable have to use the whole thing, including "connection_start" - that one is supposed to detect connection timeout, otherwise it will freeze on any request with failed connection - unfortunately there does not seem to be a way how to detect this in any other way.

(You can check, IMO all you need is to do HttpRequest on non-existing host - I think it will freeze, forever waiting for connection to finish).

It may seem srange, but HttpRequest doesn't freeze on inexistent URL. It seem to return very

quickly returning empty string, which looks like correct behaviour to me.

View Forum Message <> Reply to Message

OK, it is some time since I have added that timeout check, so perhaps the constellation of conditions for the freeze is more complex. But I do remember freezing in Win32... In any case, I think 20s timeout for connection would not hurt.

Tested /not thoroughly/ the proposed changes on another FreeBSD system (different hardware, different FreeBSD version). Everything seems to be OK.

Mirek, Core/Socket.cpp @ 519 looks like an error:
return c == c == SOCKERR(EWOULDBLOCK) || c == SOCKERR(EAGAIN);
