I tried everything, but it isn't straight forward for me.

This really needs a simple example. I understand sockets in console, but in GUI it seems you need to use threads.

How can you build a simple TCP/IP GUI chat that can act as client or server and send/receive messages?

Thanks

Hello Lectus

Few weeks ago I began to prepare some functions to communicate different programs in different computers using sockets (in plain words, I am a dummy in sockets).

Based in U++ Reference/SocketClient and SocketServer it was very simple. It is also very easy to use threads in U++ (just following a couple of simple rules: 1. debug your code before being multithreaded, 2. do not share variables but if you do it, use for example INTERLOCKED), so including in the same program the client and a multi threaded server has been straightforward.

Where are the problems you find?

Hello Koldo, I agree Lectus.

IMO, it is generally a better practice to use sockets with threads in a GUI application, but U++ needs a basic single-threaded non-blocking client/server socket example too. While I can use a traditional low level platform dependent socket routines to handle nonblocking socket operations, I have to admit that I find U++ TcpSocket class a bit confusing. A code snippet or a barebone example on, say, how to handle basic nonblocking read()/Get() and write()/put() operations with TcpSocket, and how to cancel or do "other stuff" when socket would block (e.g, canceling the operation) would be really useful.

Regards.

Hello Oblivion and Lectus

I cannot answer to that properly because I am not an expert in sockets.

Anyway I have prepared some classes that work for me very well including a multithreaded server, with few code, just three sheets of paper when printed. I have done some homemade stress tests and it has worked as expected.

If you are interested I can send you a copy of this in the end of August because now I am on holidays and I would like to prepare a simple GUI for it.
