Could someone post an example on how is WhenArrayAction used? I tried looking in the ArrayCtrl examples with no luck.

the help states that is:

"called whenever array source data changes (after insert / delete / edit)"

However it does not tell how does one knows what happened and in what rows it happened.

IMHO, this callback is designed to inform you that data has changed. No matter how. To get position you can call GetCursor(). It is not hard to figure out what happened. You just need to know number of records before this callback. If you check number of records inside of this callback and calculate the difference, then you get only three different values: -1, 0, +1, which mean deleted, changed, added.
