Subject: Implementing a crash handler

Hello,

I'm implementing a crash handler for my application. I used `SetUnhandledExceptionFilter` to let unhandled SEH exceptions flow into my own exception handler. My exception handler then executes a `TopWindow` with information about the crash. This works great when the exception is raised on the UI thread. The window may be created in the exception handler and it blocks until the window is closed.

I'm facing trouble with exceptions that are raised on a different thread. Using the `Dispatch` package from Bazaar (`DispatcherCB`) I tried to let the (asynchronous) exception handler dispatch the exception to the main window that uses `PostCallback` to invoke the window execution. Using an `Atomic` I tried to have the exception handler block until the window is closed but this only works partially.

With this solution, the next problems are:

When the exception is raised on the UI thread, the application enters an infinite loop, because the exception handler is blocking execution; When using `EXCEPTION_EXECUTE_HANDLER` to return from the exception handler, the application should terminate. Since I implemented the above described solution, the application does not terminate after the crash handler window is closed and destroyed.

I'm really having trouble with this. Is there an easier way to get the crash handler to be executed in a thread-safe way? Maybe there is an easier C++ builtin way?

Thanks a lot!
