When I start the IDE it comes up with a "Select main package" screen. From where does it get its list of assemblies and packages ?

Suppose I want to open a package not in its list. How do I do that ? If I choose "Cancel" the IDE closes and if I choose New Package it does not allow me to select an already created package somewhere else.

Assemblies are created/edited/... by right clicking in the left pane of the "Select main package" dialog. The physical information is stored in the IDE configuration directory (~/.u++/theide on linux, not sure where it is on windows) as *.var files. You can edit/create them there as well, if you prefer that.
